## Lecture 9

## Kruskal-Wallis: Tied Ranks

2. The corrected value of $\mathrm{H}_{\mathrm{adj}}=\mathrm{H} / \mathrm{D}$,
a. This serves to increase the value of H and make the result more likely to be significant. $\qquad$
b. Why? Uncorrected scores are unnecessarily conservative.
c. An example of how tied ranks makes it more difficult to distinguish between group medians.

## Kruskal-Wallis: Example

$\qquad$

1. The numbers of beetles on three colors of flowers $\qquad$

|  | flowers |  |
| :--- | :--- | :--- |
| White | Yellow | Purple |
|  |  |  |
| 96 | 82 | 115 |
| 128 | 124 | 149 |
| 83 | 132 | 166 |
| 61 | 135 | 147 |
| 101 | 109 |  |

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

| Example With Tied Ranks |  |  |
| :---: | :---: | :---: |
| White | Yellow | Purple |
| $\rightarrow 96$ | 82 | 115 |
| 128 | 124 | 149 |
| 83 | 135 | 166 |
| 61 | 135 | $\rightarrow 135$ |
| $\rightarrow 96$ | 109 |  |
| Note tied ranks |  |  |

## Kruskal-Wallis: Example

$\qquad$
2. Rank the scores as a single series from lowest to highest. $\qquad$

| White | Yellow | Purple |
| :---: | :--- | :--- |
|  |  |  |
| 4 | 2 | 7 |
| 9 | 8 | 13 |
| 3 | 10 | 14 |
| 1 | 11 | 12 |
| 5 | 6 | - |
|  | - | - |
| $R_{j}$ | 22 | 37 |

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

## Example With Tied Ranks

2. Rank the scores from lowest to highest

|  | White | Yellow | Purple |
| :--- | :--- | :--- | :--- |
| 4.5 | 2 | 7 |  |
| 9 | 8 | 13 |  |
| 3 | 11 | 14 |  |
| 1 | 11 | 11 |  |
| $R_{\text {R }}$ | $\frac{4.5}{22}$ | $\frac{6}{38}$ |  |
|  |  |  |  |

tied scores: $(4+5) / 2=4.5 ;(10+11+12) / 3=11$

## Example With Tied Ranks

3. Note that rank scores $\mathrm{R}_{2-3}$ have changed:

|  | White | Yellow | Purple |
| :---: | :---: | :---: | :---: |
|  | 4.5 | 2 | 7 |
|  | 9 | 8 | 13 |
|  | 3 | 11 | 14 |
|  | 1 | 11 | 11 |
|  | 4.5 | 6 |  |
| $\mathrm{R}_{\mathrm{j}}$ | 22 | 38 (37) | 45 (46) |

a. This is because of tied ranks in these columns.

## Kruskal-Wallis: Example

3. Then use K-W formula to

| White | Yellow | Purple |
| :---: | :---: | :---: |
| 4 | 2 | 7 |
| 9 | 8 | 13 |
| 3 1 | ${ }_{11}^{10}$ | 12 |
| 5 | 6 |  |
| - | - | - |
| $\mathrm{R}_{\mathrm{j}}{ }^{22}$ | ${ }^{37}$ | 46 |
| $\mathrm{H}=$ | $\frac{1}{1)} \stackrel{a}{\stackrel{a}{2}} \frac{\mathrm{R}_{\mathrm{i}}{ }^{2}}{\mathrm{n}_{\mathrm{j}} \mathrm{df}=a-1}$ | ( $\mathrm{N}+1$ ) |
| $\left.+(37)^{2} / 5+(46)^{2} / 4\right]-3(14+1)$ |  |  |
| $\mathrm{H}_{[.05 ; 5,5,4]}=5.64, \mathrm{P}<0.05$. |  |  |

calculate H :

$$
\begin{gathered}
\mathrm{D}=1-\frac{\Sigma \mathrm{T}}{\mathrm{~N}^{3}-\mathrm{N}} \quad \text { And Now, } \\
\Sigma \mathrm{T}=\left[(2)^{3}-2\right]+\left[(3)^{3}-3\right]=6+24=30 \\
\mathrm{D}=1-\left\{30 /\left[(14)^{3}-14\right]\right\}=.989 \\
\text { Thus, } \\
\mathrm{H}_{\mathrm{adj}}=\mathrm{H} / \mathrm{D} \\
=6.4 / .989=6.47 \\
\mathrm{P}<0.049 .
\end{gathered}
$$

$\qquad$

## Measures of Association

1. Are used to examine the relationship (covariance) between two or more variables. $\qquad$
a. Analogous to regression/correlation analysis.
b. Relationships are based on ranks rather than raw/transformed scores.

## Measures of Association

1. The two best known are:
a. Spearman's rank order correlation.
b. Kendall's rank order correlation.
2. This latter is useful because it is possible to obtain partial correlation coefficients.
3. Useful for path analysis with small data sets
c. Also:
4. Multiple variable procedure: Kendall's coefficient of concordance.

## Spearman's $r_{\mathrm{S}}$ : Method

1. Consider a herd of red deer in which male mating success depends on his fighting success relative to other males.
a. What is the relationship between number of fights and mating success?

## Spearman＇s $r_{\mathrm{S}}$ ：Method

1．Rank variables $X$ and $Y$ separately from lowest to highest． $\qquad$
Ind．非Fights 非Mates $\qquad$
A 27
B $\quad 14$
C $\quad 5$
D 11
E 2
6
4
1
5
3 $\qquad$
$\qquad$
$\qquad$
$\qquad$

## Spearman＇s $r_{\mathrm{s}}$ ：Method

$\qquad$
2．Calculate the deviations for X and $\mathrm{Y}(d)$ ， then $d^{2}$ and $\Sigma d^{2}$ ：

Ind．非Fights

| \＃Mates | d | $\mathrm{d}^{2}$ |
| :--- | ---: | :--- |
|  |  |  |
| 5 | 0 | 0 |
| 3 | 1 | 1 |
| 1 | 1 | 1 |
| 4 | -1 | 1 |
| 2 | -1 | 1 |

$\qquad$

| A | 5 | 5 | 0 | 0 |
| ---: | ---: | ---: | ---: | ---: |
| B | 4 | 3 | 1 | 1 |
| C | 2 | 1 | 1 | 1 |
| D | 3 | 4 | -1 | 1 |
| E | 1 | 2 | -1 | 1 |

$\qquad$
$\qquad$
－

$$
4=\Sigma d^{2}
$$

## Spearman＇s $r_{\mathrm{s}}$ ：Method

$\qquad$ Then，

If：
$\qquad$
$r_{s}=1-\frac{{ }^{N} \sum_{d_{i}}{ }^{2}}{N^{3}-N}$
$=1$－

$$
\frac{6(4)}{5^{3}-5}
$$

$=1-.196$
$\qquad$
$\qquad$
$\qquad$

## Spearman's $r_{\mathrm{S}}$ : Result

$$
r_{\mathrm{S}}=.803
$$

a. Look up significance in Table Q for $\mathrm{N}<25$.

| N : | : 35 | . 20 | . 10 | :025 | :01 | . 010 | ${ }_{\text {.0025 }}$ | .002 | .0005 (one-tailed .001 Ctuse-tailed |

## Spearman's $r_{\mathrm{s}}$ : Tied ranks

1. The effect of ties is to reduce the sum of squares $\Sigma x^{2}$ below $\left(\mathrm{N}^{3}-\mathrm{N}\right) / 12$.
a. The correction for ties is:
$T_{i}=\left(t^{3}-t\right) / 12$, for the i-th tied rank, and

$$
\Sigma x^{2^{\prime}}=\left(\mathrm{N}^{3}-\mathrm{N}\right) / 12-\Sigma \mathrm{T}
$$

b. Do the same for $\Sigma y^{2}\left(\right.$ corrected $\left.=\Sigma y^{2}\right)$.

## Spearman's $r_{\mathrm{S}}$ : Tied ranks

1. these values are then substituted into originally derived formula for $r_{\mathrm{S}}$ :

$$
r_{\mathrm{S}}=\frac{\Sigma x^{2^{\prime}}+\Sigma y^{2^{\prime}}-\Sigma d^{2}}{\sqrt{2\left(\Sigma x^{2} \Sigma y^{\prime}\right)}}
$$

## Spearman's $r_{\mathrm{S}}$ : Tied ranks

2. For Large samples: $(\mathrm{N}>10)$
a. $t=r_{\mathrm{S}} \sqrt{\left[(\mathrm{N}-2) /\left(1-r_{\mathrm{S}}\right)\right.}$
b. This value is distributed as Student's $t$ with $\mathrm{df}=\mathrm{N}-2$
c. This table is in S\&R

## Derivation of Spearman's $r_{\mathrm{S}}$

$\qquad$

1. This permits visualization of similarity with Pearson's parametric $r$.
2. Imagine two sets of variables $X_{i}$ and $Y_{i}$
a. Their relationship can be determined by arranging them in pairs and taking the difference between them:

$$
d_{\mathrm{i}}=\mathrm{X}_{\mathrm{i}}-\mathrm{Y}_{\mathrm{i}}
$$

## Derivation of Spearman's $r_{\mathrm{S}}$

$$
d_{\mathrm{i}}=\mathrm{X}_{\mathrm{i}}-\mathrm{Y}_{\mathrm{i}}
$$

1. If the relationship is perfect, every $d_{\mathrm{i}}=0$.
2. Deviations from 0 indicate how good or bad the correlation is.
3. Raw scores are difficult to use because - and + scores could cancel.
a. Thus, $d_{\mathrm{i}}^{2}$ provides a better estimate for each pair of the deviation from a perfect correlation.
b. Also, with large $d_{\mathrm{i}}$ 's, the larger $\Sigma d_{\mathrm{i}}^{2}$ will be.

## Derivation of Spearman's $r_{\mathrm{S}}$

> 3. If $x=\left(\boldsymbol{X}-\mathrm{X}_{\mathrm{i}}\right)$ and $y=\left(\boldsymbol{Y}-\mathrm{Y}_{\mathrm{i}}\right)$,
> Where $\boldsymbol{X}=\Sigma \mathrm{X}_{\mathrm{i}} / \mathrm{n}_{\mathrm{i}}$ and $\boldsymbol{Y}=\Sigma \mathrm{Y}_{\mathrm{i}}^{\prime} / \mathrm{n}_{\mathrm{i}}$
a. Then the general expression for a parametric correlation coefficient is:

$$
r=\frac{\Sigma x y}{\sqrt{\left(\Sigma x^{2} \Sigma y^{2}\right)}}
$$

b. this expression measures the degree to which two variables are correlated.

## To See This,

1. Imagine a variable, y , plotted on itself.
2. The general equation then becomes:

$$
r=\frac{\Sigma(y)(y)}{\sqrt{\left(\Sigma y^{2} \Sigma y^{2}\right)}}=1
$$

## For a Nonparametric Solution

$\qquad$

1. Assume $X_{i}$ and $Y_{i}$ are ranks.
2. Then, sum of these integers is:
$\qquad$

$$
\Sigma X_{i}=N(N+1) / 2
$$

2. Really?
$1+2+3+4+5=15 ; \mathrm{N}=5$
$5(5+1) / 2=30 / 2=15$

> Also,
> 3. The sum of their squares is:
> $\Sigma \mathrm{X}_{\mathrm{i}}{ }^{2}=\frac{\mathrm{N}(\mathrm{N}+1)(2 \mathrm{~N}+1)}{6}$
> 4. Really?
> $1^{2}+2^{2}+3^{2}+4^{2}+5^{2}=55 ; \mathrm{N}=5$
> $[5(5+1)][(2)(5)+1] / 6=(30)(11) / 6=55$

## Then,

5. It is clear that the expressions used to calculate $r_{\mathrm{S}}$ are simply what arises from sums $\qquad$ of integers or their squares.

Also, since
$\Sigma x^{2}=\Sigma\left(X-X_{i}\right)^{2}=\Sigma \mathrm{X}_{\mathrm{i}}{ }^{2}-\left[\left(\Sigma \mathrm{X}_{\mathrm{i}}\right)^{2}\right] / \mathrm{N}$,
i.e., the expression for the sum of the squared $\qquad$ deviations from the mean (a way of expressing central tendency in parametric statistics),

## So,

1. Using the equivalent nonparametric expression:
$\Sigma x^{2}=\frac{\mathrm{N}(\mathrm{N}+1)(2 \mathrm{~N}+1)}{6}-\frac{\mathrm{N}(\mathrm{N}+1)^{2}}{4}$

$$
=\left(\mathrm{N}^{3}-\mathrm{N}\right) / 12
$$

1. and similarly, $\Sigma y^{2}=\left(\mathrm{N}^{3}-\mathrm{N}\right) / 12$

| Now, |
| :---: |
| 2. Because |
| $d=x-y$ |
| Then, |
| $d^{2}=(x-y)^{2}=x^{2}-2 x y+y^{2}$ |
| for each $d_{\mathrm{i}}$, so, |
| $\Sigma d^{2}=\Sigma x^{2}+\Sigma y^{2}-2 \Sigma x y$ |
|  |

## But,

3. In theory,
$r=\frac{\Sigma x y}{\sqrt{\left(\Sigma x^{2} \Sigma y^{2}\right)}}=r_{\mathrm{S}}$
if $X_{i}$ and $Y_{i}$ are ranks.

## Thus, By Substitution,

4. The expression for $\Sigma d^{2}$ becomes:

$$
\Sigma d^{2}=\Sigma x^{2}+\Sigma y^{2}-2 r_{\mathrm{S}} \sqrt{\left(\Sigma x^{2} \Sigma y^{2}\right)}
$$

> Thus,

$$
r_{\mathrm{S}}=\frac{\Sigma x^{2}+\Sigma y^{2}-\Sigma d^{2}}{2 \sqrt{\left(\Sigma x^{2} \Sigma y^{2}\right)}}
$$

and by substitution of $\Sigma x^{2}=\left(\mathrm{N}^{3}-\mathrm{N}\right) / 12=\Sigma y^{2}$
into this equation,

$$
\begin{array}{r}
\text { We Have, } \\
r_{S}=1-\frac{6 \Sigma d_{i}^{2}}{N^{3}-N}
\end{array}
$$
