

Chapter 5

Organization and Expression of Immunoglobulin Genes

Genetic Models

- **How to account for:**
 - 1) Vast diversity of antibody specificities
 - 2) Presence of Variable regions at the amino end of Heavy and Light chains, and a Constant region at the carboxyl end
 - 3) Existence of isotypes (different Heavy chains) with same antigenic specificity

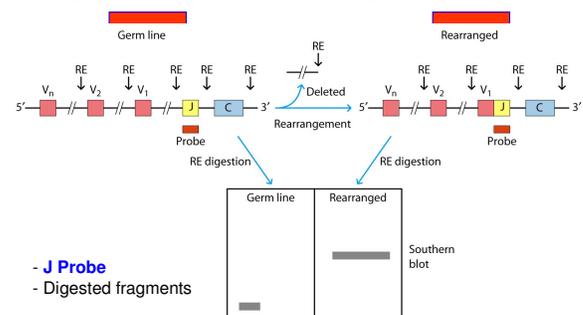

Models to Explain Antibody Diversity

- 1) **The Germ Line Theory:** “genome possesses a large repertoire of antibody genes to account for all the diversity”
- 2) **The Somatic Variation Theory:** “genome possesses a relatively small number of antibody genes and diversity is generated by mutation and recombination of these genes during somatic development”

The two-gene model

- Developed by Dreyer and Bennet in 1965
- Two separate genes code for the Heavy and Light chains. One codes for the V region and the other for the C region
- These genes come together during at the DNA level to form a continuous message
- There are thousands of V genes in germ line but only one gene for the C region

Tonegawa (1976): Immunoglobulin gene rearrangement

Three genetic loci encode immunoglobulin molecules:

- Two loci encoding the light chains
 - kappa locus
 - lambda locus

- One locus encoding the heavy chain

These three loci are located on different chromosomes.

TABLE 5-1 CHROMOSOMAL LOCATIONS OF IMMUNOGLOBULIN GENES IN HUMAN AND MOUSE

Gene	Chromosome	
	Human	Mouse
λ Light chain	22	16
κ Light chain	2	6
Heavy chain	14	12

Multigene Families

- **Light Chains:** V, J and C gene segments.
- **Lambda:** Humans (30V, 4J and 7C genes)
- **Kappa:** Humans (40V, 5J and 1C genes)
- **Heavy Chains:** V, D, J and C gene segments
- **Heavy Chains:** Humans (50V, 25D, 6J and 8 C genes)

Number of functional gene segments in human immunoglobulin loci

Segment	Light chains		Heavy chain
	κ	λ	H
Variable (V)	40	30	40
Diversity (D)	0	0	25
Joining (J)	5	4	6

Figure 4-3 Immunobiology, 6/e. (© Garland Science 2005)

The loci encoding immunoglobulins have a unique structure.
- composed of "gene segments"

- The heavy chain locus has multiple V (variable) segments, multiple D (diversity) segments, multiple J (joining) segments and multiple C (constant) segments.

During maturation, one of each V, D and J segment is randomly "chosen" and used to encode the final antibody molecule.

Germline configuration of the heavy chain locus (mice)

Heavy chain locus

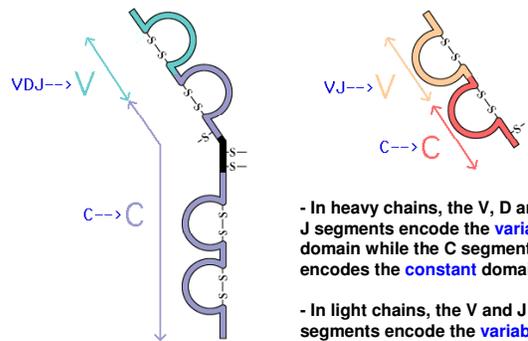

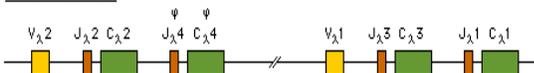

The kappa locus has a similar structure - BUT - does not have D segments.

A kappa chain is encoded by one V segment, one J segment and one C segment.

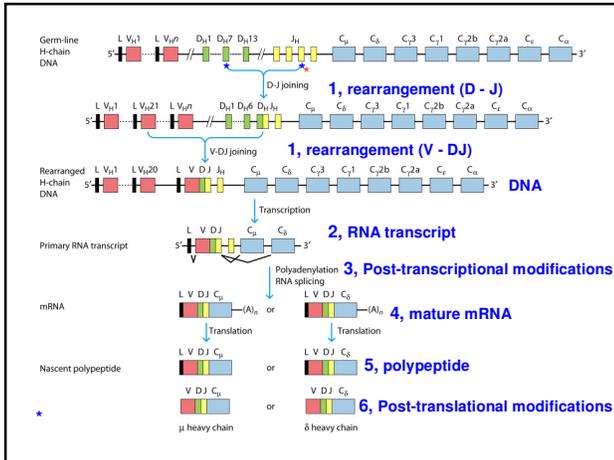

Kappa locus

Lambda locus

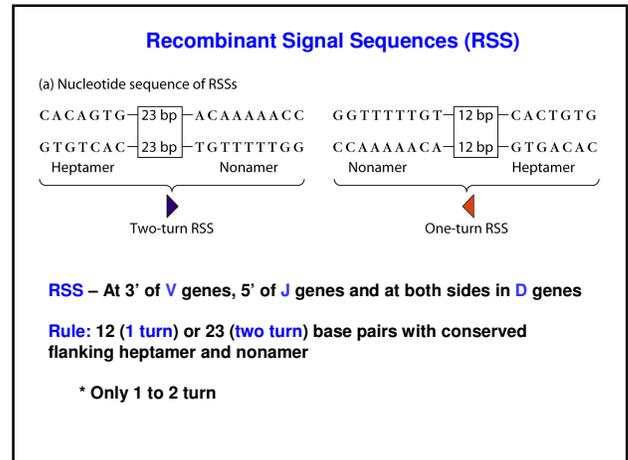

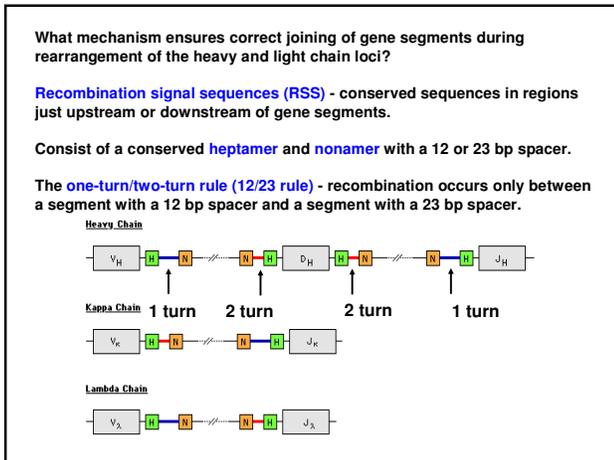

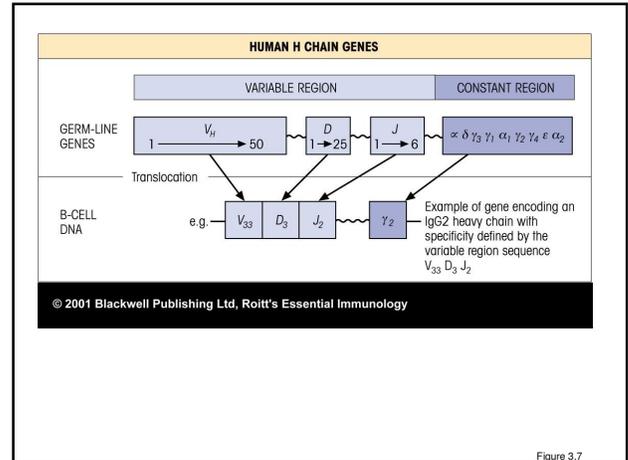

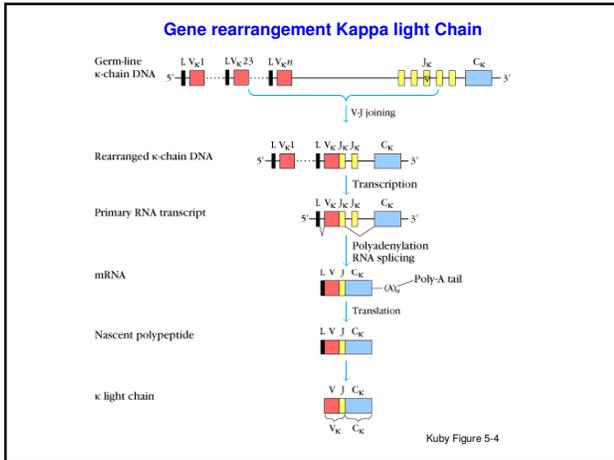

- In heavy chains, the V, D and J segments encode the variable domain while the C segment encodes the constant domain.
- In light chains, the V and J segments encode the variable domain while the C segment encodes the constant domain.

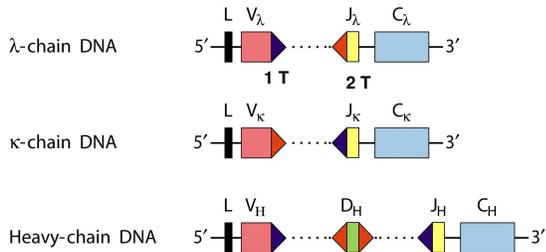

The kappa and lambda loci undergo similar rearrangement.

Since there are no D segments, there is a single V-->J rearrangement.

The final light chain mRNA contains one VJC unit.

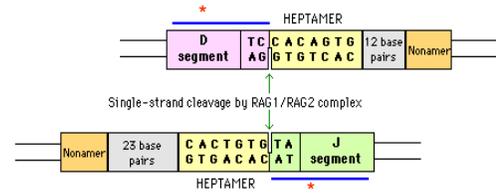

(b) Location of RSSs in germ-line immunoglobulin DNA

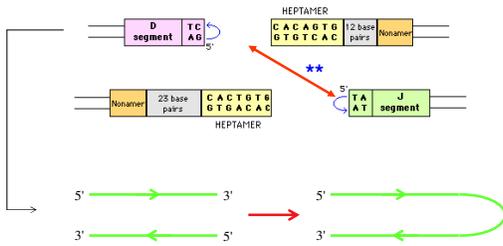

- Rearrangement of gene segments is mediated by the RAG1/RAG2 enzyme complex (recombinases).
- The RAG1/RAG2 complex recognizes the heptamer/nonamer sequences and cuts one strand of the DNA.

Step 1: The RAG1/RAG2 complex recognizes the RSS's and mediates single-strand DNA cleavage

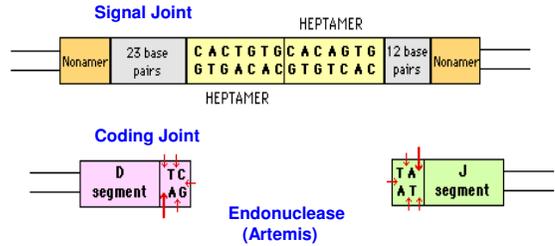

A hairpin forms...

Step 2: The 5' cut end of the cut strand reacts with the uncut strand resulting in a double-stranded break and hairpin formation

The hairpin is cut at a random site...

Step 3: The heptamer sequences are ligated. An endonuclease cleaves the hairpin at a random site.

Palindromic sequences may form...

Step 4: Endonuclease cleavage may result in short palindromes - additional nucleotides resulting from this are known as P-nucleotides.

Terminal deoxynucleotidyl transferase (Tdt)

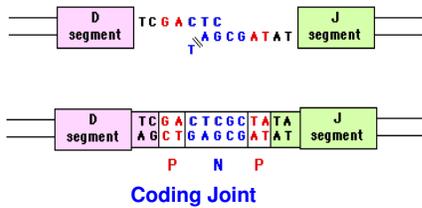

An enzyme that randomly adds in nucleotides during joining of coding gene segments.

Step 5: TdT adds N-nucleotides randomly to the single stranded ends.

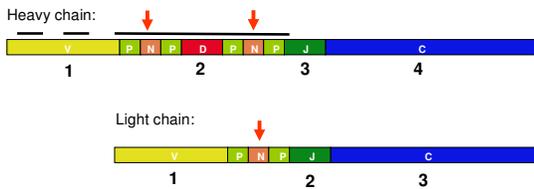

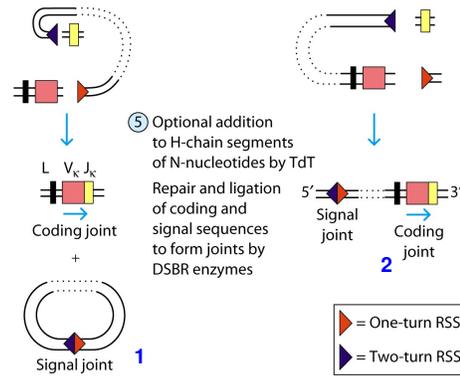

The join is repaired...

Step 6: The two single-stranded ends pair. Unpaired nucleotides are trimmed by an exonuclease and the coding joint is repaired

Note: Keep in mind that this random rearrangement can lead to **PRODUCTIVE** and **NON-PRODUCTIVE** gene rearrangements

(a) Deletional joining (b) Inversional joining

The final "gene" encoding the antibody produced by a B cell (and T cells) consists of a number of different segments.

This process of recombination of different gene segments and addition of **P** and **N nucleotides** ensures that an enormous number of different antigen specificities are possible.

Generation of antibody diversity

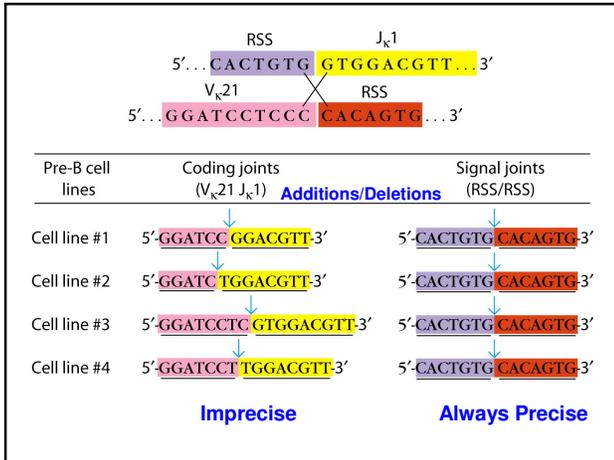

1. Multiple germline V, D and J gene segments
2. Combinatorial V-J and V-D-J joining
3. Somatic hypermutation
4. Junctional flexibility
5. P-nucleotide addition
6. N-nucleotide addition
7. Combinatorial association of heavy and light chains

Combinatorial V-J and V-D-J joining

- Humans:
 - Heavy Chain: V (51), D (27), J (6) = 8262
 - Light Chain: Kappa – V (40), J (5) = 200
 - Lambda – V(30), J (4) = 120
- $8262 \times (200 \times 120) = 2.64 \times 10^6$

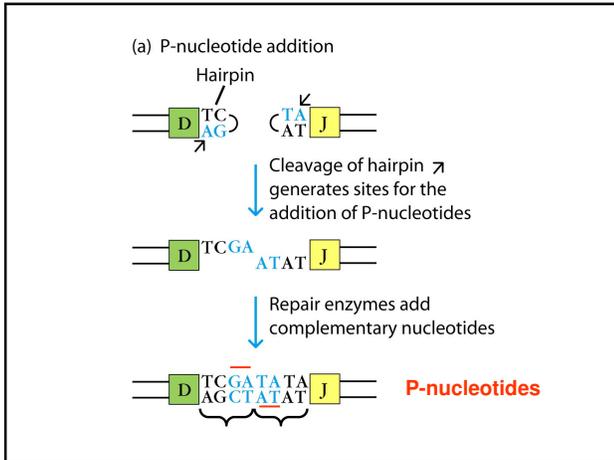

Junctional flexibility

- Generated through V, D and J combinations
- Joining of Recombination Signal Sequences = Signal Joint
- Joining of Coding Sequences = Coding Joint
- **Signal Joints** ALWAYS joined precisely, but joining of **Coding Joints** is IMPRECISE
- Good = Antibody diversity
- BAD = Non-productive rearrangements

P-nucleotide addition

- Cleavage of the Hairpin at the end of the coding sequence by endonuclease (Artemis) is random
- Generates a short single strand of nucleotides **at the end** of the Coding sequence
- Addition of complementary nucleotides to this strand forms a palindrome sequence (**P nucleotides**)

N-nucleotide addition

- Once complementary nucleotides to this strand have been added to form a palindrome sequence (**P nucleotides**)
- The enzyme TdT (terminal deoxynucleotidyl transferase) fills the gap with **N nucleotides**.
- This enzyme can add randomly up to **15 N nucleotides** (non-genomic)
- N nucleotides can be added to the **D-J** and **V-DJ** in the H chain.
- This mechanism does not happen in the Light chain

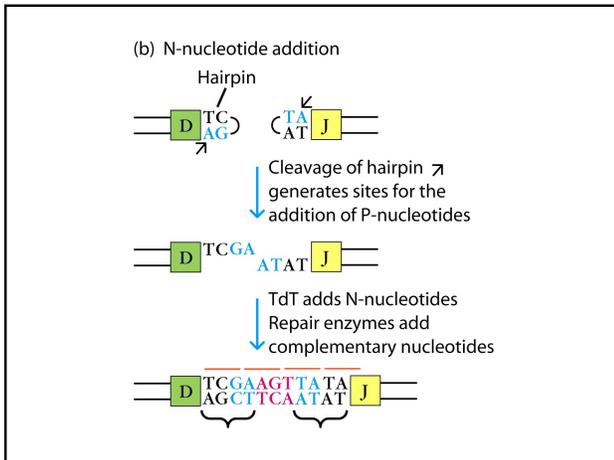

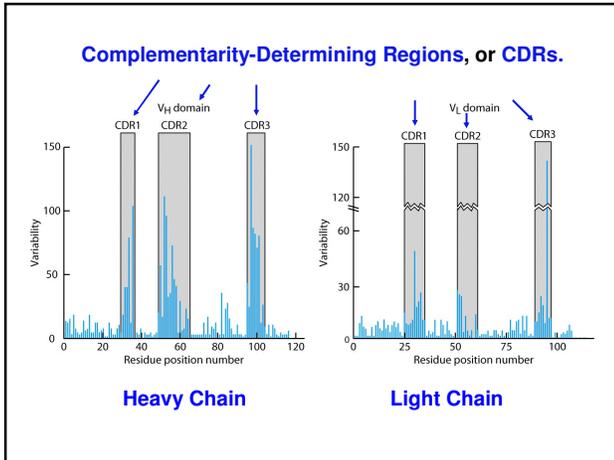

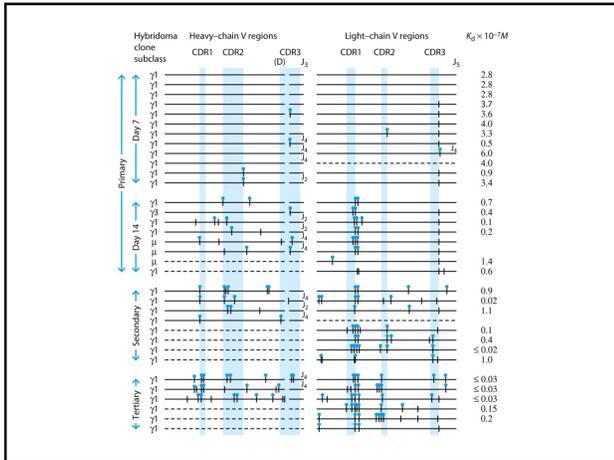

TABLE 5-3 Sources of sequence variation in complementarity-determining regions of immunoglobulin heavy- and light-chain genes*

Source of variation	CDR1	CDR2	CDR3	****
Sequence encoded by:	V segment	V segment	V _H -J _H junction; V _H -D _H -J _H junctions	
Junctional flexibility	-	-	+	
P-nucleotide addition	-	-	+	
N-nucleotide addition*	-	-	+	
Somatic hypermutation	+	+	+	

*N-nucleotide addition occurs only in heavy-chain DNA.

- ## Somatic Hypermutation
- Generated **point mutations** in gene segments for variable regions (VDJ and VJ segments)
 - Takes place in secondary lymphoid organs (~ 1 week after contact with antigen)
 - In mature B cells mutations are clustered in CDRs regions
 - Affinity maturation**- selection process leading to survival of those B cells with high affinity for the antigen

Generation of Diversity

	B cell receptor (Immunoglobulin)	
	Heavy	Light
V gene segments	1000	300
D gene segments	15	-
J gene segments	4	4
N region insertion	++	-
Junctional diversity	+++	+
Somatic mutation	+	+
	$V \times D \times J$	$V \times J$
	$1000 \times 15 \times 4$	300×4
Total	6×10^4	1.2×10^3
Combinatorial association	7.2×10^7	

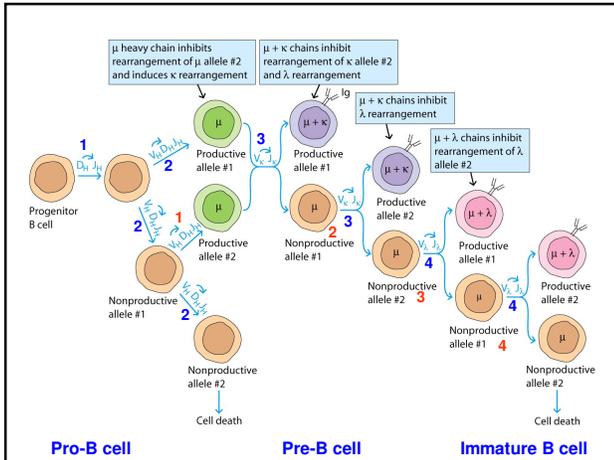

2.64×10^6

- Ag independent process**
- Clonal selection**

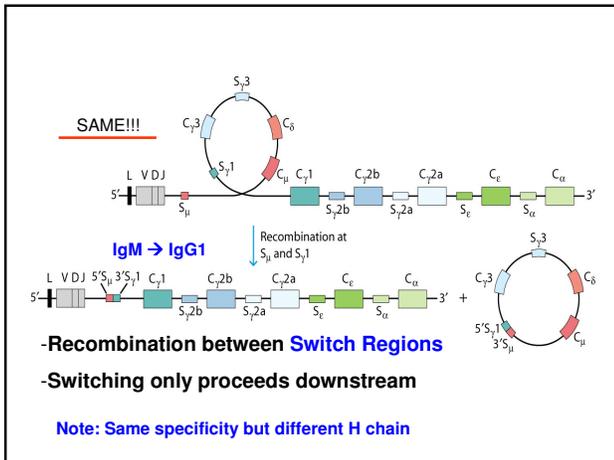

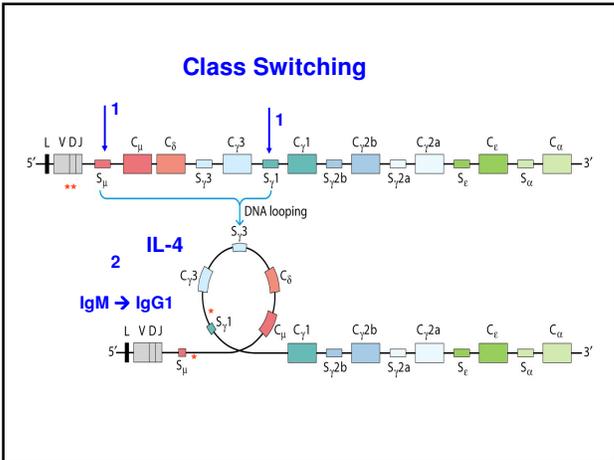

ALLELIC EXCLUSION:

- We have two copies (alleles) of each Ig gene - one inherited from our father and one from our mother.
- In most cases, both genes are expressed.
- But Antibody genes are different! Only one heavy chain allele and one light chain allele is expressed!!!
- This is termed **allelic exclusion** (one allele is excluded). Once a productive arrangement is made, the other allele is suppressed
- Why? To ensure that each B cell makes antibody of a single specificity.

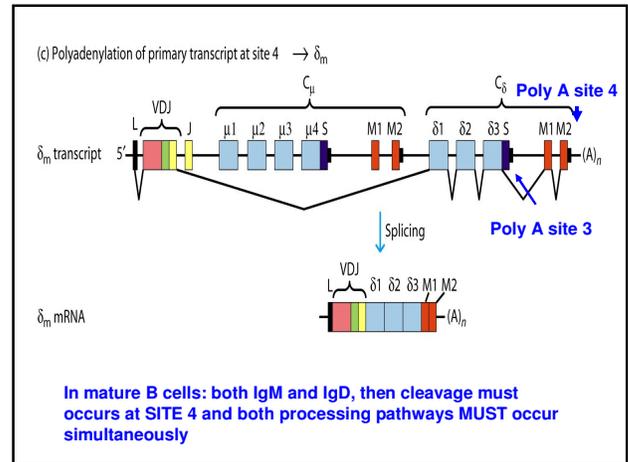

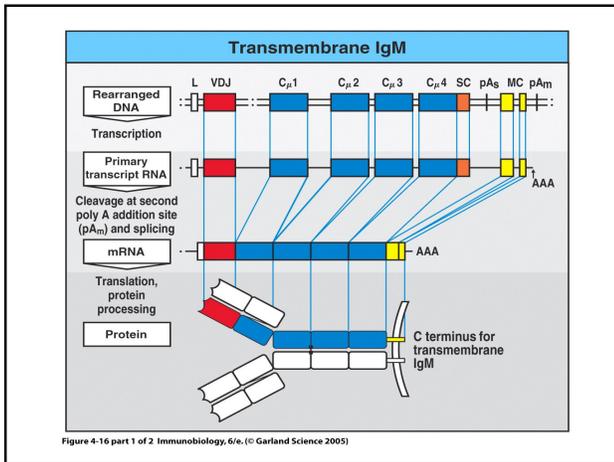

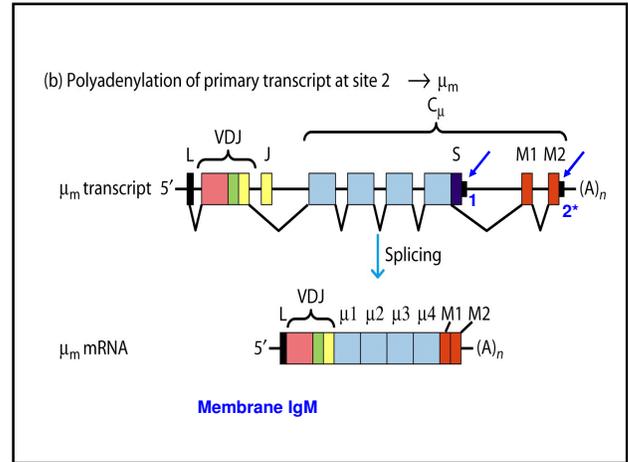

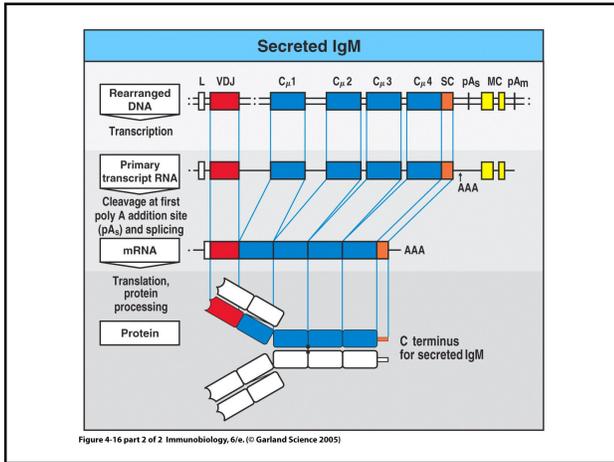

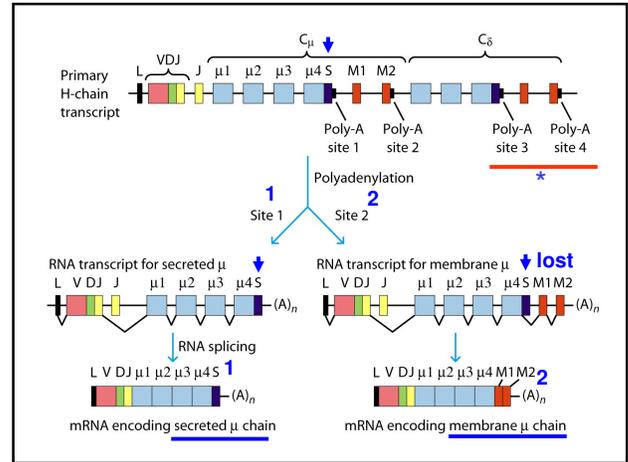

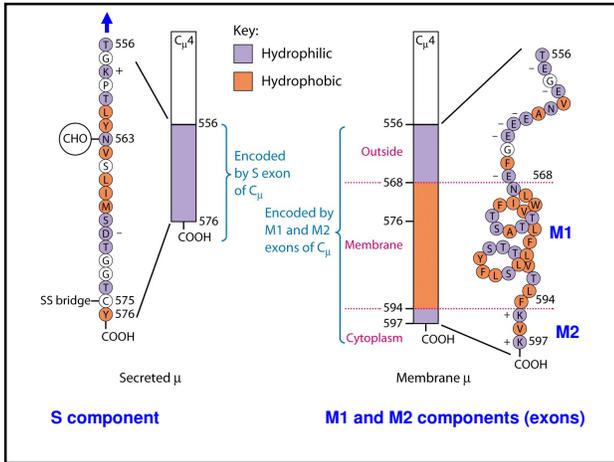

- ## Class Switching
- Antigen stimulation of a B cells → Antibodies with same variable Heavy (VDJ) with any C_H gene segment
 - Process dependent on **Switch Regions**
 - Switch Regions (2-3 kb) are located upstream from each C_H segment, **except IgD (C_δ)**
 - Process driven by cytokines:
 - IL-4 → IgM to IgG1 or IgE
 - IFN-γ → IgM to IgG2a
 - **Players in regulation:** 1) switch regions, 2) switch recombinases, 3) cytokine signals

- ## Expression of membrane or secreted Immunoglobulin
- In mature B cells → **membrane forms**; in Plasma cells → **secreted forms**
 - Process depends on **differential processing** of primary transcript
 - Remember: IgG, IgD, IgA (3 C_H domains), IgM and IgA (4 C_H domains).
 - Domain 3/4 contains the **Secretory** (hydrophilic) nucleotide sequence (**S**) at its 3'.
 - Two Exons at 3' encode the **M1** (trans-membrane) and **M2** (cytoplasmic) segments.
 - Primary transcript contains two **PolyA sites**: If cleavage at Poly A site I = **Secreted Form**. If cleavage at PolyA site 2 = **Membrane Form**

The End

From Immunity: The Immune Response in Infectious and Inflammatory Disease
by DeFranco, Locksley and Robertson

- RAG-1/RAG-2 cleave ONE strand of DNA
- This occurs at the border of the RSS heptamer and the coding gene
- The 3' OH group attacks a phosphodiester bond on the other DNA strand
- This results in hairpin DNA strand on the coding region.
- Other enzymes get involved and remove the "junk" and bring together the coding regions

Junctional Diversity:

From Immunity: The Immune Response in Infectious and Inflammatory Disease
by DeFranco, Locksley and Robertson

- Terminal deoxynucleotidyl transferase (TdT) is important for creating junctional diversity
- What are **SIGNAL JOINTS** and **CODING JOINTS**?
- Hairpin must be opened → the enzyme **Artemis**
- Cleavage is random and can happen at any site in the hairpin
- Replication results in a short inverted repeat or palindrome = **P nucleotides**
- TdT can now introduce random nucleotides into the coding joints = **N nucleotides**
- Keep in mind that all this introduced variability may result in functional and non-functional Ig (or TCR) genes.
